**Abstract.** Early-type galaxies (ETGs) host a hot ISM produced mainly by stellar winds, and heated by Type Ia supernovae and the thermalization of stellar motions. High resolution 2D hydrodynamical simulations showed that ordered rotation in the stellar component results in the formation of a centrifugally supported cold equatorial disc. In a recent numerical investigation we found that subsequent generations of stars are formed in this cold disc; this process consumes most of the cold gas, leaving at the present epoch cold masses comparable to those observed. Most of the new stellar mass formed a few Gyrs ago, and resides in a disc.

**Keywords.** stars: formation; ISM: evolution; ISM: kinematics and dynamics; galaxies: elliptical and lenticular, cD; galaxies: ISM; galaxies: structure

## 1. Introduction

High resolution 2D hydrodynamical simulations with the ZEUS-MP2 code showed that ordered rotation in the stellar component affects significantly the evolution of the hot ISM in ETGs, and, among other effects, results in the formation of a centrifugally supported cold equatorial disc (Negri et al. 2014, hereafter N14). This disc can be extended ( $\sim 0.5 - 10$  kpc radius), and as massive as  $10^{10}M_{\odot}$  in the biggest ETGs. Indeed there is evidence that  $\sim 50\%$  of massive ETGs host significant quantities of cold gas (Davis et al. 2011, Serra et al. 2014), often in settled configurations, sharing the same kinematics of the stars, consistent with an internal origin. Also, the cold gas seems to provide material for low level star formation (hereafter SF); and, in the ATLAS<sup>3D</sup> sample, molecular gas, SF and young stellar populations are detected only in fast rotators (Sarzi et al. 2013, Davis et al. 2014). We then added the possibility for the gas to form stars to the simulations of N14, to explore whether SF can bring the amount of cold gas in the models more in agreement with observed values, and whether it can explain the low-level SF activity currently seen to be ongoing in rotating systems.

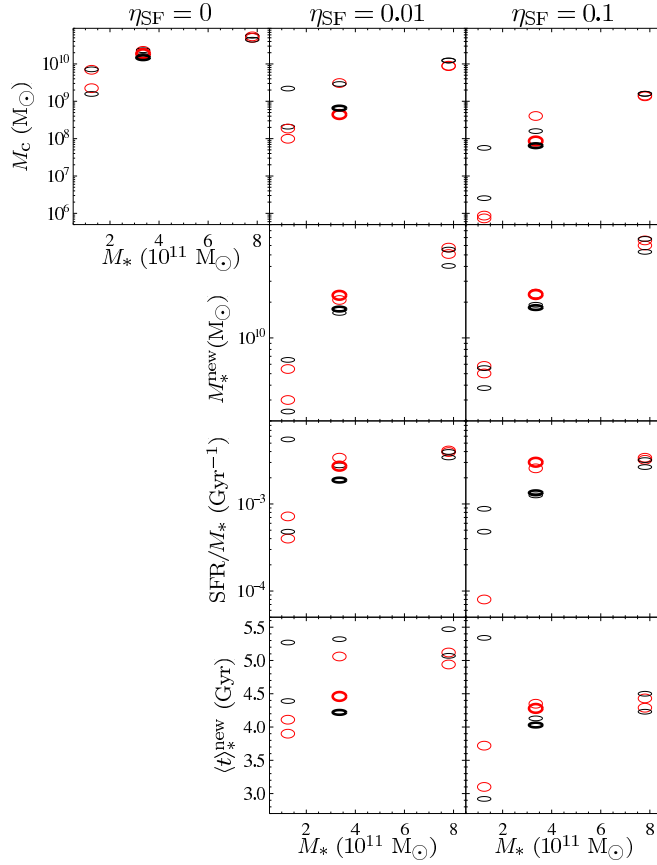

## 2. The models and the results

Hydrodynamical simulations were run for a representative subset of 12 rotating models from N14, including in the code the removal of cold gas, and the injection of mass, momentum and energy appropriate for the newly forming stellar population (Negri et al. 2015). SF was implemented by subtracting gas from the grid, at an adopted rate per unit volume of  $\dot{\rho}_{\text{SF}} = \eta_{\text{SF}}\rho/t_{\text{SF}}$ , where  $\rho$  is the gas density,  $\eta_{\text{SF}}$  is the SF efficiency ( $\eta_{\text{SF}} = 0.01$  and  $0.1$  were adopted), and  $t_{\text{SF}}$  is the maximum between the cooling timescale and the dynamical timescale. In a typical (cyclical) evolution, gas injected by the stellar population accumulates until radiative losses become catastrophic, significant amounts

of cold material are produced, and SF is enhanced. At the end the cold gas mass  $M_c$  is much reduced in the models with SF, and the mass in new stars  $M_*^{\text{new}}$  is close to the  $M_c$  values of the models without SF (Fig. 1). The new stars reside mostly in a disc, and could be related to a younger, more metal rich disk component observed in fast rotators (Cappellari et al. 2013). Most of  $M_*^{\text{new}}$  formed a few Gyrs ago; the SF rate at the present epoch is low ( $\leq 0.1 M_\odot \text{yr}^{-1}$ ), as observed, at least for model ETGs of stellar mass  $< 10^{11} M_\odot$  (Fig. 1). The adopted SF recipe reproduces the slope of the Kennicutt-Schmidt relation, and even its normalization for  $\eta_{\text{SF}} = 0.01$  (Negri et al. 2015).
